

Applications of Percent

Objective 1

Solve an Applied Percent Problem

Applied percent problems can generally be solved using the following structured format.

(A percent) of (a total) is (a portion).

$$\left(\begin{array}{c} \text{\%} \\ \downarrow \end{array} \right) \cdot \left(\begin{array}{c} \text{Total} \\ \downarrow \end{array} \right) = \left(\begin{array}{c} \text{Portion} \end{array} \right)$$

Let's now use this structured format to solve the following problem.

A basketball player makes **72** out of **90** free throws. What percent of free throws does the basketball player make?

In this problem, the basket player attempts 90 total free throws. Therefore, **90** is our total. The player makes 72 of the 90 free throws. Therefore, **72** is our portion.

We can now set up an equation using our structured format where we let the variable x represent the unknown percent.

$$\begin{array}{ccccccc}
 (\%) & \cdot & (\text{Total}) & = & (\text{Portion}) \\
 \swarrow & & \swarrow & & \swarrow \\
 x & \cdot & 90 & = & 72
 \end{array}$$

Here we have the equation $x \cdot 90 = 72$ or $90x = 72$. Solving for x we get, $x = \frac{72}{90}$ or $x = 0.8$ as a decimal.

Because x represents a percent, we convert the decimal number to a percent by moving the decimal point two places to the right. This gives us $x = 80\%$.

To properly answer the question, we can write the following: **The basketball player makes 80% of attempted free throws.**

Example 1: If 40 students enrolled in a music class but only 34 completed the course, what percent of students completed the course?

Example 2: Watermelon is 91% water. How many pounds of a 12 pound watermelon is water?

$$\begin{array}{ccccccc} (\%) \cdot (\text{Total}) = (\text{Portion}) \\ \swarrow \quad \searrow \quad \downarrow \quad \swarrow \quad \searrow \\ 0.91 \cdot 12 = x \end{array}$$

Example 3: If Thao deposits 30% of her paycheck into a savings account and the amount she deposits is \$255, what was the total amount of her paycheck?

$$\begin{array}{ccccccc} (\%) \cdot (\text{Total}) = (\text{Portion}) \\ \swarrow \quad \searrow \quad \downarrow \quad \swarrow \quad \searrow \\ 0.30 \cdot x = 255 \end{array}$$

In the Health Care Career field, many calculations involve "mixtures or solutions" that are made of water and some other ingredient.

For example, a liquid solution that is marked 75% sodium means that the solution is 75% water and 25% sodium.

Similarly, a 1% iodine solution means that the solution is 99% water and 1% iodine.

Example 4: How much sodium is in a 60 milliliter bottle labeled 75% sodium?

$$\begin{array}{ccccccc} (\%) & \cdot & (\text{Total}) & = & (\text{Portion}) \\ \swarrow & & \swarrow & & \swarrow \\ 0.75 & \cdot & 60 & = & x \end{array}$$

Example 5: If 46% of a solution is water and there is 184 milliliters of water in the solution, how many milliliters is the total solution?

$$(\%) \cdot (\text{Total}) = (\text{Portion})$$

Example 6: How much hydrochloric acid (HCl) is in a 70 milliliter bottle that is labeled 34% HCl?

$$(\%) \cdot (\text{Total}) = (\text{Portion})$$
